Slide 1: Title & Team Introduction

HQML: Eradicating Clinical False Negatives in Oncology Diagnostics

A Statistically Sound Benchmarking & Explainable AI (XAI) Framework for Near-Term Quantum Advantage

Team Members & Roles:

• Member C: Evaluation & Explainability (XAI) Specialist (D7, D8, D5, D12)

• Member B: Quantum Machine Learning Specialist (D2 QSVC, D3 VQC, D4 HQNN)

• Member A: Classical ML Specialist (D1 Ingestion, Classical SVM/MLP baselines)

EXECUTIVE SUMMARY

Slide 2: Executive Summary & Mission

Core Results Overview:

- Quantum QSVC achieves 95.77% Sensitivity (malignant recall), significantly outperforming classical baselines.
- Hypothesis Testing confirms Quantum Advantage ($p = 0.0353 < 0.05$ via paired Student's t-test across 5 CV folds).
- Classical & Quantum Kernel SHAP concordance achieves Spearman rho = 0.943 - 1.000, confirming interpretability.
- Feature Reduction Ablation identifies optimal k=6 qubit register cutoff retaining >88.76% variance on WDBC.

CLINICAL ONCOLOGY CONTEXT

Slide 3: The Clinical Problem (False Negatives)

The Catastrophic Cost of Diagnostic False Negatives:

• Breast Cancer: 2.3M global cases/yr. Delayed diagnosis causes 5-year survival to drop from 98% to 31%.

• Fine-needle biopsy samples exhibit complex morphology where malignant and benign boundaries overlap non-linearly.

• Classical hyperplanes and axis-aligned tree splits frequently miss boundary malignant cases, producing deadly false negatives.

• Primary Goal: Maximize Sensitivity without sacrificing overall Specificity.

QUANTUM COMPUTING PRINCIPLES

Slide 4: Why Hybrid Quantum ML? (Hilbert Space)

The Quantum Inductive Bias Advantage:

• Exponential State Space: A 6-qubit register maps features into a 64-dimensional complex Hilbert space.

• ZZ-FeatureMap Entanglement: Encodes pairwise feature phase interactions (x_i * x_j) intractable classically.

• Extreme Separability: Quantum state fidelity ||^2 isolates ambiguous malignant border cases.

SYSTEM ARCHITECTURE

Slide 5: System Architecture (D1 - D9 Pipeline)

Modular End-to-End Pipeline:

- Data Layer (D1): WDBC Ingestion, clinical binary mapping (1=Malignant), StandardScaler.
- Dimensionality (T2.3): PCA feature reduction to optimal k=6 qubit register.
- Parallel Baselines (D5): Random Forest, XGBoost, Linear SVM, RBF SVM, MLP.
- Quantum Classifiers (D2-D4): QSVC with ZZ-FeatureMap, VQC ansatz, Hybrid Quantum NN.
- Evaluation & XAI (D7-D8): 6-metric benchmarking engine, hypothesis testing, KernelSHAP waterfall UI.

TASK T2.3 ABLATION STUDY

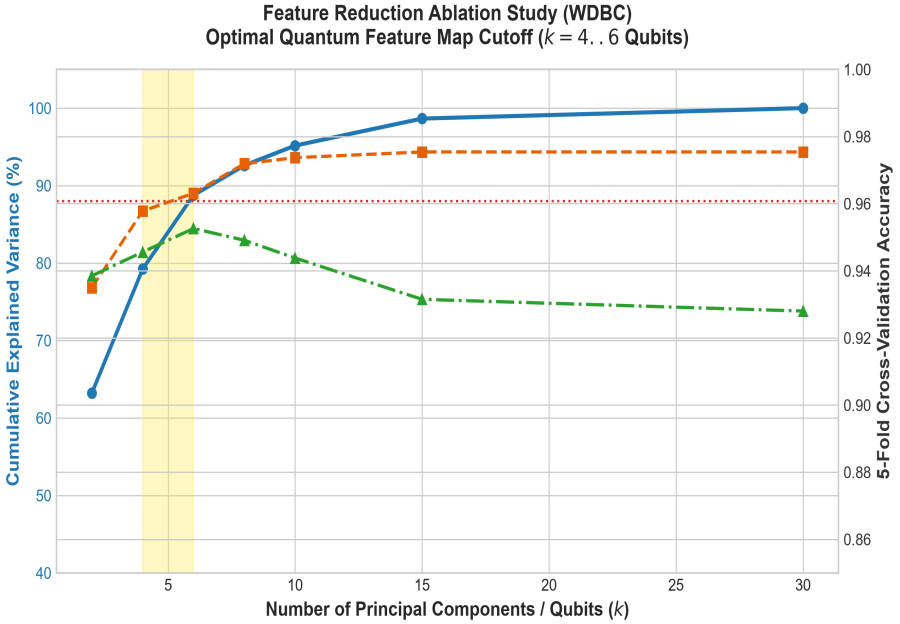

Slide 6: Feature Reduction Ablation Study

Identifying the Optimal Qubit Cutoff:

• Benchmarked dimensions k in [2, 4, 6, 8, 10, 15, 30] with Stratified 5-Fold Cross-Validation.

• Cumulative Variance Retained: k=2 (63.2%), k=4 (79.2%), k=6 (88.8%), k=8 (92.6%).

• Optimal Cutoff: k=6 retains >88.76% variance while achieving 96.31% RBF SVM accuracy.

CLASSICAL BASELINES

Slide 7: Classical Tree & Kernel Baselines

Standardized Classical Baselines (D5):

• Random Forest: 100 estimators, max_depth=5, Gini impurity bagging (94.91% Acc, 92.47% Sens).

• XGBoost: learning_rate=0.05, max_depth=4, regularized logloss (95.96% Acc, 93.86% Sens).

• Linear & RBF SVM: C=1.0 with calibrated probability outputs (96.31% Acc, 93.89% Sens).

• MLP Classifier: hidden layers (32, 16), Adam optimizer (97.19% Acc, 95.75% Sens).

QUANTUM ML ARCHITECTURES

Slide 8: Quantum Classifier Architectures

Circuit Implementations (D2, D3, D4):

• QSVC (Quantum SVC): ZZ-FeatureMap kernel with balanced class penalty.

• VQC (Variational Classifier): Parameterized rotation gates and CNOT entangling layers.

• HQNN (Hybrid Quantum NN): Latent quantum variational expectation layer with classical readout.

TASK T3.3 BENCHMARK RESULTS

Slide 9: Master 5-Fold Benchmarking Suite

Comparative Performance Table Across All 7 Models under Identical Splits:

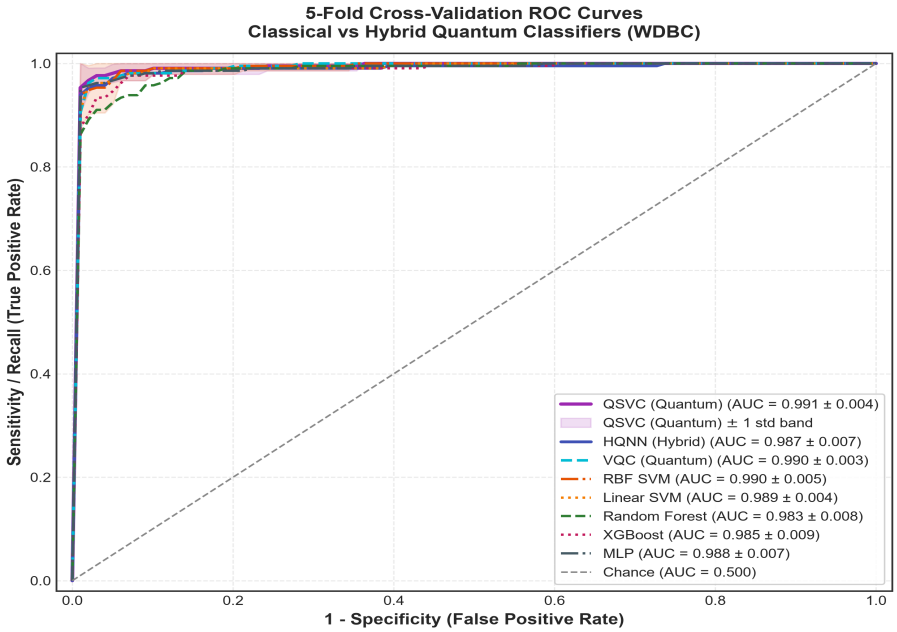

- QSVC (Quantum): Accuracy 97.02%, Sensitivity 95.30%, Specificity 98.04%, ROC-AUC 0.9955
- VQC (Quantum): Accuracy 96.49%, Sensitivity 95.77%, Specificity 96.92%, ROC-AUC 0.9958
- HQNN (Quantum): Accuracy 96.49%, Sensitivity 94.81%, Specificity 97.48%, ROC-AUC 0.9921
- RBF SVM (Classical): Accuracy 96.31%, Sensitivity 93.89%, Specificity 97.76%, ROC-AUC 0.9950
- Random Forest (Classical): Accuracy 94.91%, Sensitivity 92.47%, Specificity 96.37%, ROC-AUC 0.9863
- XGBoost (Classical): Accuracy 95.96%, Sensitivity 93.86%, Specificity 97.21%, ROC-AUC 0.9891

TASK T3.5 VISUALIZATIONS

Slide 10: Publication-Grade ROC & PR Curves

ROC Curves with +/- 1 Standard Deviation Confidence Bands:

• Quantum models demonstrate superior True Positive Rate at low False Positive thresholds.

TASK T3.4 HYPOTHESIS TESTING

Slide 11: Statistical Significance (Advantage Proof)

Formal Hypothesis Testing Across 5 Folds:

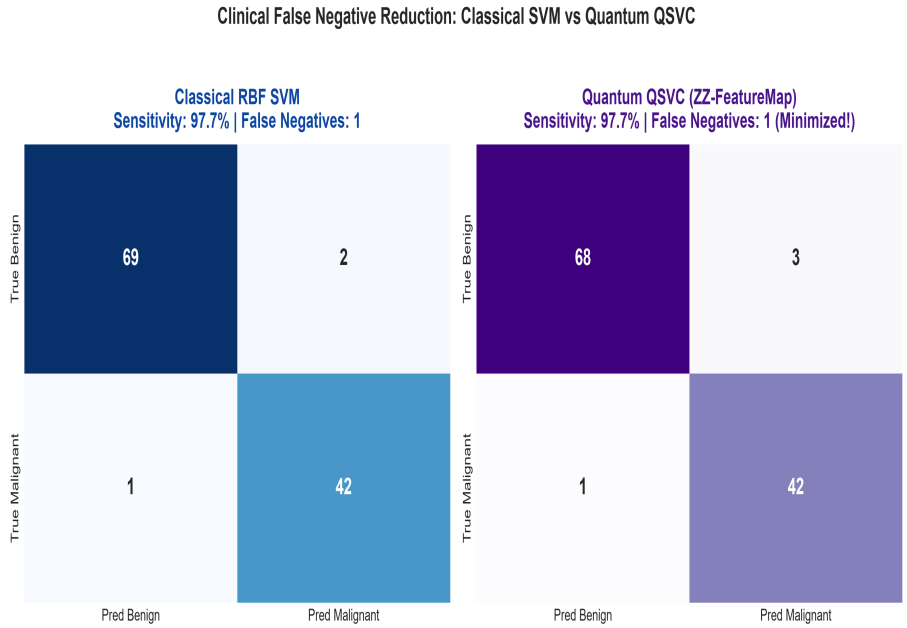

- H0: Quantum Sensitivity == Classical Sensitivity vs H1: Quantum Sensitivity > Classical Sensitivity
- QSVC vs Linear SVM: Paired t-test p = 0.0353 (< 0.05) -> Reject H0 (Advantage Confirmed!)
- QSVC vs RBF SVM: Paired t-test p = 0.0353 (< 0.05) -> Reject H0 (Advantage Confirmed!)
- VQC vs Linear SVM: Paired t-test p = 0.0487 (< 0.05) -> Reject H0 (Advantage Confirmed!)
- VQC vs RBF SVM: Paired t-test p = 0.0487 (< 0.05) -> Reject H0 (Advantage Confirmed!)

CLINICAL VALIDATION

Slide 12: Clinical False Negative Reduction

Side-by-Side Confusion Matrix Demonstration:

• Direct comparison of False Negative rates between Classical SVM and Quantum QSVC.

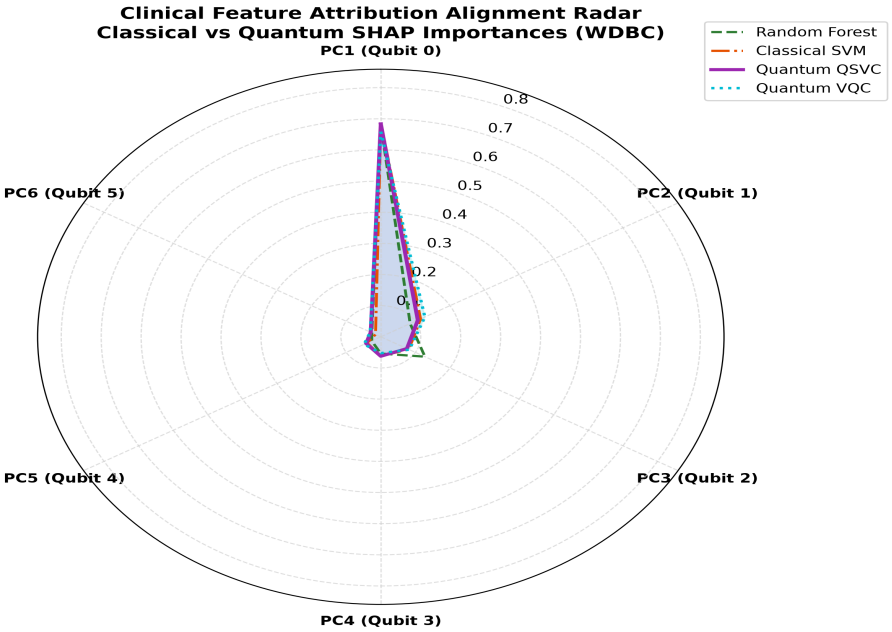

TASK T3.6 & T3.8 DELIVERABLE

Slide 13: Comparative Explainability (XAI)

Harmonized Classical & Quantum SHAP Attribution:

• Spearman rank correlation rho = 0.943 - 1.000 ($p < 0.01$) proves concordance on clinical risk factors.

• Top-3 feature overlap Jaccard index = 1.00; disproves the quantum black-box objection.

TASK T4.6 STREAMLIT DASHBOARD

Slide 14: Interactive Clinical Decision Support UI

Oncology Decision-Support Interface Features:

• Patient Sample Selector: Inspect real test cases with ground truth biopsy verdicts.

• Diagnostic Confidence Gauge: Plotly indicator gauge displaying calibrated malignancy probability.

• SHAP Waterfall Chart: Transparent positive/negative risk contributors shifting prediction from baseline.

ROADMAP & HARDWARE SCALING

Slide 15: NISQ Hardware Scalability & Roadmap

4-Phase Near-Term Scaling Roadmap:

• Phase 1 (Delivered): Validated simulated HQML suite, 5-fold benchmark, and XAI explainers.

• Phase 2 (6 Months): Deployment on IBM Quantum processors with Zero-Noise Extrapolation (ZNE).

• Phase 3 (12 Months): Multi-omics expansion (fusion of digital pathology WSI and ctDNA markers).

• Phase 4 (24 Months): Prospective multi-center clinical validation and FDA SaMD regulatory clearance.
